

# 'You won't believe what happened next!'

## Building a News Article Validation Tool with NLP

K Iwasaki

Sohag Desai

Phat Doan

### Abstract

Reading news has become incredibly more convenient with the rise of the Internet, as readers can quickly access in real-time quality journalism at a push of a button. However, as the rate of information grows exponentially, our human brain is frequently overwhelmed by too many choices. This, in turn, leads us to find ourselves looking for patterns, trying to simplify issues and giving precedence to opinions that reinforce what we already believe to be true. Our project aims to leverage Natural Language Processing techniques to create a tool that enables news consumers to quickly identify non-clickbait news. We break down our proposed tool into two separate classifiers: clickbait detection at the title level, and text summarization for clickbait classification at article content level. We attempt to show that clickbait headlines tend to differ drastically from the text summary of the article content in order to draw the reader to the article.

## 1 Introduction

Clickbait news articles are endemic for online readers. These articles often contain misleading titles or purposely withholding information required to understand the content. The term also describe a news headline which will tempt a user to follow by using provocative and catchy wording. Their main purpose is to entice users to click on the articles to generate revenues, the content on the landing page is usually of low quality. At the same time, the content of these articles is often of low quality. A few examples of clickbait titles extracted from our dataset are: "*Should I Get Bings?*", "*Which TV Female Friend Group Do You Belong In?*".

Non-clickbait titles that we identified are: "*White House Announces International Meetings to Address Energy and Climate Issues*", "*France Approves Crackdown on Internet Piracy*".

As reading news has become incredibly more convenient with the rise of the Internet and the rate of information grows exponentially, our human brain is frequently overwhelmed by too many choices. At the same time, readers are often frustrated with news articles often not living up to the expectation due to misleading titles and exaggerating the content on the landing page. Our project aims to leverage Natural Language Processing techniques to create a tool that enables news consumers to quickly identify non-clickbait news that are of their interests. Given an article title and its content, we will classify it into one of two classes: clickbait or not clickbait. We divide our problem into two tasks: classification at the title level, and summary of news article content for title comparison. To evaluate the efficacy of our model, we conduct experiments on two datasets. First dataset is provided by a team member's company that consist of 15,999 clickbait and 16,000 non-clickbait headlines. Second dataset is scraped from Reddit `/r/savedyouaclick` for clickbait articles and `/r/news` for non-clickbait articles.

Our intended contributions to the current research: 1/ build an open-source clickbait dataset that contains article contents in addition to the headlines. 2/ propose a new approach to clickbait classification by applying text summarization technique to article contents and comparing the summarization results to article title. Our team firmly believes that while title-level clickbait classification is superior at the moment, untrustworthy content generators will eventually outsmart these classifications. Therefore, it would be important to forge ahead and contribute to current research of content-level clickbait classification.

## 2 Background

Much research has been done on clickbait classification in the recent years. Most notable works are (Anand et al., 2016) (Biyani et al., 2016) and (Chakraborty et al., 2016). (Chakraborty et al., 2016), utilizes SVM, decision tree, and random forest to predict clickbait with great results of 0.97 ROC-AUC. (Anand et al., 2016), explored several neural network models such as Recurrent Neural Network (RNN) architectures, Gated Recurrent Units (GRU) and standard RNNs and achieved 0.99 ROC-AUC with word embedding LSTM neural network. Both teams utilized dataset comprising 15,000 news headlines released by Chakraborty in 2016 as described in (Chakraborty et al., 2016) for their models. However, this research focused solely on clickbait classification at the title level. (Biyani et al., 2016), expanded the research to include title, URL and article body as input for the classification. (Biyani et al., 2016), used novel informality features for clickbait classification, which have not been previously used, and showed that these features are the most important. For the body, (Biyani et al., 2016) applied textual similarity algorithm between titles and top sentences of the body to detect clickbait. Through an ensemble classifier, engineered features, and 7677 word features, (Biyani et al., 2016) achieved 0.755 precision and 0.760 recall on the test set. While this is not as strong a classifier as title-only classification, its approach is arguably more holistic by taking consideration of both title and article content.

Text summarization is to concisely recapitulate a text. Current research indicates two approaches to summarization: extractive and abstractive. Extractive methods build summaries exclusively using phrases and/or sentences from the source text. This can be formulated using algorithms. Abstractive methods, on the other hand, utilize different words and phrases not appeared in the source text for their summarization. This is inherently more difficult to build from a machine learning algorithm perspective. Most research in the past has focus on extractive (Kupiec et al., 1995); (Sagionet et al., 2013). On the abstractive front, recent research has been successful with the use of sequence-to-sequence models such as recurrent neural networks (RNNs) to both ingest, digest, and freely generate text (Chopra et al., 2016), (Nallapati et al., 2016), (Rush et al., 2015), (Zeng et al.,

2016). From our observation, (See et al., 2017) created a model using Pointer-Generator + Coverage algorithm that outperformed all previously researched models. (See et al., 2017), evaluated their models with the standard ROUGE metric (Lin, 2004), reporting the F1 scores for ROUGE-1, ROUGE-2 and ROUGE-L. These metrics respectively measure the word-overlap, bigram-overlap, and longest common sequence between the reference summary and the summary to be evaluated.

## 3 Method

### 3.1 Proposed work

Given an article title and its content, classify it into one of two classes: clickbait or not clickbait. We divide our problem into two tasks: classification at title-level and summary of a news articles' major topics for document representation. Our work expands previous work to include title, abstract, and news content as input for our detection algorithms. We use word embeddings, Convolutional Neural Network (CNN) and hyperparameter tuning as the main methodology for our clickbait classifier at the title level. For text summarization, we use (See et al., 2017) as the foundation of our work to form the hypothetical title, which is then compared with the actual article title using textual similarity techniques.

To evaluate the efficacy of our model, we conduct experiments on two datasets. First dataset is provided by a team member's company that consists of 15,999 clickbait and 16,000 non-clickbait headlines. Second dataset is scraped from Reddit `/r/savedyouaclick` for clickbait articles and `/r/news` for non-clickbait articles. We build a custom scraper and parser to get the headlines and article content from Reddit through its json source code. The two mentioned subreddits provide a naturally curated place for clickbait and non-clickbait articles. `/r/savedyouaclick` is moderated by Reddit moderators as a forum for sharing interesting clickbait articles. Redditors would share a clickbait article in this general format: *"5 Reasons Tinder Is Dead And Is Never Coming Back | It isn't, the writer just deleted it from their phone"*. The first part before "I" contains the actual article title, while the second part is the Redditor's summarization of the article content. This setting automatically provides us a great training data set for our clickbait classification at the content level. The `/r/news`, on the other hand, provides mod-

erated balance-viewed, non-political news from around the world and will serve as the validated non-clickbait training set.

Using this Reddit-scraped dataset, we will build a news summarization that we then can compare with the actual article's title to determine if it is a clickbait or not.

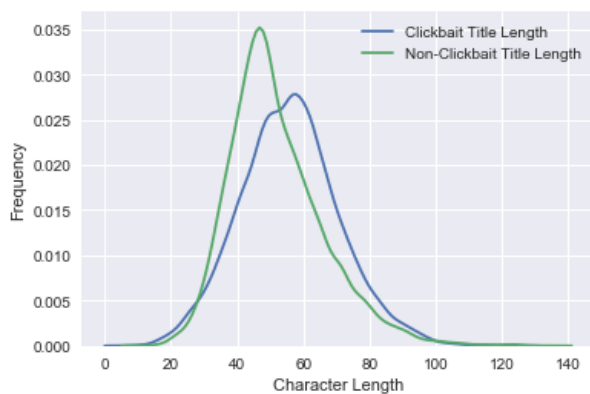

#### 4 Exploratory Data Analysis

Conducting Exploratory Data Analysis on the first dataset, we performed the following operations. First, we prepared the data by splitting the dataset into test and train sets with an 80/20 split. In the first dataset, we have a total of 32,000 training samples, of which 15,999 are labeled clickbait and 16,001 are non-clickbait. The train set comprises 25,600 samples and the test set comprises 6,400.

Our next step was to query the data. We examined the following aspects of the data in order to identify features that we could use to classify the data: 1/ character count of title; 2/ word count of title; 3/ common words used; 4/ most frequent punctuation characters used.

We observed some interesting patterns which can be used towards feature engineering.

Figure 1 shows a plot of character count distribution for clickbait and non-clickbait samples.

**Figure 1:** Title Length in Characters v/s Frequency for Clickbait and Non-Clickbait

Table 1 shows the top 25 words used in clickbait and non-clickbait headlines:

Figure 2 shows a plot of word count distribution for clickbait and non-clickbait samples.

Table 2 shows the top 25 punctuation characters used in clickbait and non-clickbait headlines:

We observed the following:

- Title lengths for both word count as well as character count for non-clickbait tend to be

Rank	Clickbait		Non-Clickbait

## 5 Completed Work

### 5.1 Baseline Model: Title-Level Classification

When evaluating the approaches to tackle the clickbait classification problem, we reviewed prior work in applying Convolutional Neural Network (CNN) and Recurrent Neural Network (RNN) to this and related NLP problems.

CNN is typically used for image recognition problem and is not commonly applied to NLP. However, (Yin et al., 2017) and (Vu et al., 2016) have done work in comparing the use of CNN versus RNN for classification tasks. They report higher performance of CNN over RNN and give evidence that CNN and RNN provide complementary information. RNN computes a weighted combination of all words in the sentence; CNN extracts the most informative ngrams for the relation and only consider their resulting activations. Both (Wen et al., 2016) and (Adel et al., 2017) support CNN over GRU/LSTM for classification of long sentences.

In addition, (Yin et al., 2017) achieve better performance of attention-based CNN than attention-based LSTM for answer selection. (Dauphin et al., 2016) further argue that a fine-

tuned gated CNN can also model long context dependency, getting new state-of-the-art in language modeling above all RNN competitors.

This motivated our approach to use CNN for the clickbait classification problem. Our strategy involved preserving the structural integrity of the text and allowing the CNN to do feature engineering.

We used the following hyperparameters:

- Filter sizes: 3,4,5
- Number of filters: 512
- Dropout: 0.5
- Embedding dimension: 100
- Number of epochs: 5

We trained on 23040 samples and validated on 2560 samples. The following are the other parameters:

- Sequence length: 25,600
- Number of classes: 2
- Batch size: 32

For learning the embedding, we considered two approaches: *word2vec* and *GloVe*. The former is a predictive approach and the latter a count-based approach. Predictive models learn their vectors in order to improve their predictive ability of the loss of predicting the target words from the context words given the vector representations. Count-based models learn their vectors by essentially doing dimensionality reduction on the co-occurrence counts matrix.

*GloVe* has been extensively used and proven to be very effective. It is an unsupervised learning algorithm for obtaining vector representations for words. Training is performed on aggregated global word-word co-occurrence statistics from a corpus, and the resulting representations showcase interesting linear substructures of the word vector space. It has been trained on Wikipedia 2014 (6B words) and pre-trained word vectors are available for use. This motivated the use of *GloVe* for our embedding layer.

For our optimizer, we considered *Adagrad* and *Adam*. *Adagrad* is an algorithm for gradient-based optimization that adapts the learning rate to the parameters, performing larger updates for infrequent and smaller updates for frequent parameters.

For this reason, it is well-suited for dealing with sparse data. Adaptive Moment Estimation (*Adam*) is another method that computes adaptive learning rates for each parameter. In addition to storing an exponentially decaying average of past squared gradients, Adam also keeps an exponentially decaying average of past gradients. Since our data is not sparse we selected *Adam* over *Adagrad*.

We used the following values for optimization:

- Optimizer: adam
- Learning rate: 0.0001
- Exponential decay rate for the 1st moment estimates (beta\_1): 0.9
- Exponential decay rate for the 2nd moment estimates (beta\_2): 0.999
- Constant for numerical stability (epsilon): 1e-08
- Learning rate decay over each update cycle: 0.0001
- Loss function: binary cross-entropy
- Metrics: accuracy

Figure 3: Seq2Seq Architecture

## 5.2 Advanced Model: Content-level Summarization

For our advanced model our evaluation showed that the work done by (See et al., 2017) is the most cutting-edge and yields the best results till date on text summarization. (See et al., 2017) utilize a novel approach applying a hybrid pointer-generator network that can copy words from the source text via pointing, which aids accurate reproduction of information, while retaining the ability to produce novel words through the generator. Second, they use coverage to keep track of what has been summarized, which discourages repetition. Their approach was able to outperform the current abstractive state-of-the-art by at least 2 ROUGE points.

We began implementing this approach, but due to time limitations we remained with their baseline approach, i.e. Baseline Seq2Seq + Attention. Figure 3 shows the schematic architecture of Seq2Seq.

The key decisions to make were: for the Encoder, 1/ embedding dimensions 2/ activation function for the hidden layer 3/ recurrent layer activation function 4/ kernel initializer type 5/ recurrent layer initializer; and for the Decoder: 1/ activation function for the hidden layer 2/ recurrent layer activation function 3/ kernel initializer type 4/ dense layer initializer

Figure 4 shows the model parameters we chose for our implementation.

Figure 4: Model Parameters

## 6 Results and Discussion

### 6.1 Baseline Model: Title-Level Classification

The following are the results after our initial training and running the model:

#### 6.1.1 Confusion Matrix and Sample Accuracy

We see that the confusion matrix (Table 3) shows results that are quite reasonable with a 1.5% false negative rate (97/6400) and a 2% false positive rate (130/6400). Likewise, the sample accuracy (Table 4) shows a very good result.

Actual/Predicted	Clickbait	Non-Clickbait
Clickbait	3097	97
Non-clickbait	130	3076

Table 3: Confusion Matrix

#### 6.1.2 Model Accuracy and Loss

Running the model on the test data shows an improvement on model accuracy (Figure 5) that starts from approximately 0.94 at the first epoch, till it reaches 0.96 on the fifth epoch. As can be expected, the accuracy on training starts below 0.88 but approaches 0.97 by the fifth epoch. Conversely, the loss on training data (Figure 6) starts above 0.25 and converges to below 0.05 by the fifth epoch; and on test data, it starts at 0.15 and flattens to 0.10 by the fifth epoch.

Figure 5: Model Accuracy

#### 6.1.3 Classification Report

All the measures for the classification report (Table 5) precision, recall and f1-score show good performance of the classifier with all these measures above or equal to 0.96.

605	5 things you need to know Monday	EN_US_NATIONAL	0.999817

Table 4: Sample Accuracy

#### 6.1.4 Example Errors

The error examples reveal some deficiencies in the model. Certain words and acronyms that appear in the test set are not available in the training set, so these are missing in the pre-processed data, thus confusing the classifier. For example, the samples with ID 10 ("Timesman"), 196 ("Mouthgasm"), 308 ("Extroverted"), 345 ("Mandingo"), 460 ("Helpline", "pianist"), 694 ("HDTV"), provide examples of these types of errors. Absence of these key words and acronyms in the reverted text cause the classifier to misclassify these samples as non-clickbait when in fact they are clickbait. Other error sources could include words and punctuations that are typically used in clickbait (examples: ID 81 ("knows"), 256 ("strange"), 302 (","), 362 ("tricky")), thus causing the model to misclassify these sample as clickbait when in fact they aren't.

	precision	recall	f1-score	support
0	0.96	0.97	0.96	3194
1	0.97	0.96	0.96	3206

**Table 8: Text Summarization - Non-Clickbait**

## 6.2 Advanced Model: Content-level Summarization

### 6.2.1 Accuracy and Loss

Table 7 shows the results after training the advanced model on the team member's company dataset.

Notice that as one would expect the training loss monotonically decreases as epochs pass. However, the validation loss increases after the 40th epoch or so. This can be explained by the fact that the model is overfitting. Using dropouts can help improve the ability of the model to generalize.

### 6.2.2 Example Output

Tables 8, 9 and 10 show example outputs on the test data.

### 6.2.3 Error Analysis

Our text summarization results for both clickbait and non-clickbait turn out to be poor. The main reasons for this are insufficient training data and limitations of the basic Seq2Seq model. The model used by (See et al., 2017) would be able to eliminate a number of the errors we see with the basic Seq2Seq model.

There are two classes of primary text summarization errors that the Pointer-Generator Model with Coverage developed by (See et al., 2017) can address: 1/ the summaries sometimes reproduce factual details inaccurately 2/ The summaries sometimes repeat themselves.

For example, the model generated *texas who exposes an china of u.s. elections - her with her her*

**Table 9:** Text Summarization - Clickbait

for the fifth non-clickbait example. This is a repetition that can be eliminated by adding coverage to the basic Seq2Seq model.

Also, for the 9th non-clickbait headline: *Iranian hackers attacked college professors, US agencies and companies: Justice Department*, the generated headline based on the content was *police are russia from u.s. of*. This could be because word embeddings tend to cluster together, which may cause confusion when attempting to reconstruct the original word. It is likely "Iran" and "Russia" may be clustered together, as both countries have been alleged with hacking into US computer networks.

Using our original dataset, we ran our model on a mixture of fake and real news articles and obtained the BLEU score. This is shown in Table 10. Since BLEU measures how much the words (and/or n-grams) in the machine generated summaries appeared in the human reference summaries and ROUGE measures how much the words (and/or n-grams) in the human reference summaries appeared in the machine generated summaries, i.e. both really measure common words in the original headline and the generated headline, on a generative model we don't expect to see a high BLEU or ROUGE score, since by definition generative models are supposed to come up with a summary using novel text. Nevertheless, some of the samples 3644, 3712, 4274, 719, 3439 show a positive BLEU score.

**Table 10:** Text Summarization - Fake or Real News with BLEU score

## 7 Conclusion

This project has been a great learning experience for our team from both learning about NLP concepts and applying current trending research to build interesting applications. Our initial focus is on building a better clickbait classification model from current research. Our title-level clickbait classification performs at par with currently published models. As we expand our work, we identify and propose a novel approach of clickbait classification at content-level using abstractive text summarization. Due to several limited factors including no readily available data and time constraint, we are not able to build a satisfactory baseline model for the content-level clickbait classification. While the text summarization results are poor with the current model, we are optimistic that this novel approach of click-bait detection would become increasingly valuable as breakthroughs are continuously made in the field of summarization research.
